④ Aperture Insert.

⑤ An air admission insert (40) particularly adapted for air admission holes (25) in a combustor liner (15) in a gas turbine combustion system, comprises a pair of sleeve members, one of which (42) is inserted in the other in axial but eccentric relationship so that the sides of the sleeves contact each other, with the intervening space (45) between the sleeves being crescent shaped. The insert is positioned concentrically in a combustor liner air admission hole. Combustion air flows through the insert and into the combustor liner and axially through the crescent space to cool the insert as well as the liner hole periphery.

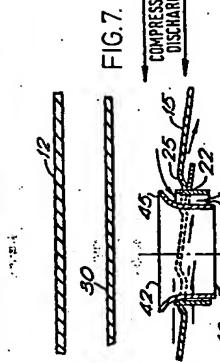

FIG. 7.

Description

This invention relates to liners which can be placed in apertures to direct air through them, such as apertures in a combustion chamber liner, as found, for example, in a gas turbine combustion system utilizing a combustion liner having air inlet apertures therein in which such inserts may be advantageously employed.

In a gas turbine combustion system, the combustion chamber or casing contains a liner which is usually of a sheet metal construction and may be of a tubular or annular configuration with one closed and one opposite open end. Fuel is ordinarily introduced into the liner at, or near the closed end while combustion air is admitted through circular rows of apertures spaced axially along the liner. These gas turbine combustion or combustor liners usually operate at extremely high temperatures and depend to a large extent on incoming combustion air from an appropriate compressor for liner cooling purposes.

As a consequence of high temperature cyclic operation and existence of thermal gradients, severe liner cracks appear about the circumference of some of the liner combustion air holes leading to premature repair and sometimes to failures necessitating replacement of the liner.

A gas turbine combustion liner of the general kind described including means to compensate for high temperature thermal expansion is disclosed and described in our U.S. Patent 4,485,630 issued to Kenworthy. The Kenworthy Patent describes the use of different construction materials, having different coefficients of expansion, in the combustion liner in order to compensate for high temperature induced stresses in the liner. A combustion liner utilizing inserts in air admission apertures thereto is illustrated and described in U.S. Patent 3,981,142 - Irwin. In the Irwin patent, metal inserts are employed in a ceramic liner hole to insulate the perimenter of an air admission hole the perimenter of which has also been coated with an insulating material, to insulate the hole perimenter from cooling effects of the entering air.

Continued occurrences of metal combustion liner cracking indicates a further need for means to prevent or minimize metal liner cracking.

In one embodiment, an insert according to the invention comprises a pair of short metal sleeves one of a larger and one of a smaller diameter. The smaller diameter sleeve fits within the larger diameter sleeve. In a non-coaxial or offset relationship so that their side walls are in contact with each other, at which point the two side walls are joined to each other. The joined assembly of the two sleeves is inserted in coaxial close fitting relationship in an combustor liner air admission hole, and fastened in

place. Incoming combustion air flows axially through the smaller diameter sleeve with a film of air flowing through the intervening space between the sleeve walls. The air film is effective in reducing temperature related high stresses at the hole periphery. The aerodynamic shape of this assembly also permits an increase in air admission to the liner over the same physical opening of a plain liner hole.

This invention will be better understood when taken in connection with the following description and drawings, in which

FIG. 1 is a schematic illustration of a gas turbine combustion system which may effectively utilize the insert of this invention.

FIG. 2 is a schematic and cross-sectional illustration of a section of a combustion liner in a gas turbine combustion system.

FIG. 3 is a schematic illustration of a top view of a section of a metal combustion liner, rotated at ninety degrees to FIG. 2, showing a combustion air admission aperture and associated liner cracking.

FIG. 4 is a schematic cross-sectional and side elevation illustration of one preferred insert of this invention.

FIG. 5 is a bottom view of the insert of FIG. 4 taken along the line 5-5 thereof.

FIG. 6 is a view of the insert of FIG. 4 positioned in a combustion liner to illustrate air flow patterns therethrough.

FIG. 7 is a cross-sectional illustration of the insert of this invention in an operative environment of the FIG. 2 liner and combustion system.

Referring now to FIG. 1, there is schematically illustrated a section 10 of a reverse flow combustion system of a gas turbine engine or power plant. In section 10 there is also illustrated a small part of an axial flow air compressor 11. Surrounding the air compressor 11 in concentric relationship thereto is a circular row of individual tubular combustion chambers or casings 12 (only one shown). Chambers 12 are arranged in axial parallel relationship to each other but spaced apart in a circular row concentrically about compressor 11. Each tubular combustion chamber 12 includes a closed end 13 and an open end 14. Concentrically positioned within and in spaced relationship to each casing 12, is a tubular combustor liner 15 also having a closed end 16 and an open end 17. Liner 15 supports and contains the combustion process in a gas turbine engine. In this connection, a gas flow duct or transition piece 18 is connected to the open end 17 of the combustor liner 15 to receive the hot gas products of combustion therefrom and duct the hot gas to a circumferential row of nozzle guide vanes 19 (only one shown) which channel and direct the hot gases from a circular cross-section at liner open end 17 to an annular segment at the circular row of guide vanes 19. Guide vanes 19 direct the hot gases through the buckets or blades at the periphery of a turbine wheel (not shown) positioned concentrically next adjacent the

circular row of vanes 19.

As illustrated by arrows in FIG. 1, air from compressor 11 flows through a compressor casing 20 and radially about the duct members 18, as illustrated by the flow arrows, and then axially into the annular space 21 between liner 15 and the wall of casting 12. Liner 15 includes a plurality of axially spaced circumferential rows of large combustion air apertures 22 commencing near closed end 16 and extending axially along liner 15, for example 3 rows of 8 apertures in each row (only 2 rows shown). A suitable liquid fuel is sprayed into liner 15 from a fuel nozzle 23 in the closed end 16 of liner 15. Fuel from nozzle 23 is mixed with combustion air from apertures 22, and ignition of the fuel air mixture takes place by means of an appropriate electrical spark ignition device 24 inserted in liner 15 adjacent closed end 16.

The combustion system as described is referred to as a reverse flow or counter current system. For example, in FIG. 1 combustion air from compressor 11, at elevated pressure, flows into annular space 21 axially in a direction towards closed end 16, and because of closed end 16, combustion air is caused to flow through apertures 22 by turning a first 90 degrees to flow through apertures 22 into liner 15 to be mixed with fuel. Ignition of the fuel air mixture generates very hot combustion gases which flow axially towards and through open end 17 of liner 15. For this reason, the combustion air which enters liner 15 through apertures 22 is caused to turn a second 90 degrees and flow axially with the hot combustion gases out of liner 15 and into transition piece 18. This final flow direction is a reverse direction, e.g. the final direction path of combustion air is in a direction 180 degrees from the direction of the combustion air flow in annular space 21, and accordingly serves as the basis for referring to the combustion system as a reverse flow system.

Linier 15 is usually of a sheet metal construction and is exposed to extremely high combustion temperatures which may cause structural failure of liner 15. For this reason, liner 15 is further provided with a plurality of axially spaced circumferential rows of smaller cooling air apertures 25 as illustrated in FIG. 2.

Referring now to FIG. 2, a cross-section of a combustion chamber or casing 12 and liner 15 is schematically illustrated. Liner 15 may be generally described as having a circumferentially corrugated wall comprising an axially extended array of smaller circular offset bands 26 leading to adjacent lateral bulges or corrugations 27. Each corrugation 27 includes at the maximum diameter of each bulge thereof, an axially extending relatively flat band part 28 which tapers axially and circumferentially in a truncated cone configuration to the next adjacent smaller offset band 26 followed by a bulge 27, band 28, band 26, etc. As more clearly shown in FIG. 2, at the maximum diameter part of the bulge 27, there is provided a circular row of smaller cooling air apertures 25. Liner 15 also includes a short internal sleeve member or band 28 which fits complementarily adjacent offset 26 at the interior of liner 15. Sleeve member 28 extends axially under an adjacent bulge

27 and the cooling apertures 25 therein, and serves as an air film along the interior wall section of liner 15 to provide, in one sense, a boundary layer of air flowing adjacent the liner wall and shielding the wall from intense combustion temperatures within liner 15. Also, a large flow sleeve 30 (FIGS. 1 and 2) may be concentrically positioned about liner 15 in the annular space 21 (FIG. 1) to serve as further air flow control means to direct air from compressor 11 more effectively to the vicinity of apertures 22 and 25. The relative location of a large aperture 22 and smaller cooling apertures 25 in a liner 15 is more clearly illustrated in FIG. 3, which is a top or outside view of the liner of FIG. 2.

Referring now to FIG. 3, a section 31 of liner 15 includes spaced axial rows 32-34 of apertures 25 as well as one large circumferential air aperture 22. Air flow from the compressor 11 (FIG. 1) passes laterally over section 31 across the plane of aperture 22 in a direction perpendicular to the horizontal rows 32, 33 and 34 of cooling air apertures 25 as illustrated by the arrow F which represents compressor air flow. An example of the noted cracking problem is illustrated by crack lines 35-40. Cracks 35-37, 38 and 39 extend radially outwardly from aperture 22 to reach an adjacent cooling aperture 25. Corresponding to the air flow as described, crack line 35 starts from the hot inside edge 22a of aperture 22 while crack 38 starts from the cold outside edge 22b of aperture 22. Such cracking appears to be continuous and leads to structural failure of the liner. Air from the compressor 11 which passes through apertures 22 maintains the perimeter of the aperture on the outside of liner 15 at a relatively cool temperature. However, the inner periphery of the aperture 22 is exposed to high intensity combustion and operates at a very high temperature. Such a temperature differential may contribute significantly to cracking or contribute to continuance of existing cracking. Further, the air flow from compressor 11 in turning the first 90 degrees as described, may be subject to flow separation from the inside edge of apertures 22 so that this edge in the 90 degree curve experiences a higher temperature than the outside edge a circumstance which also may have deleterious effects with respect to cracking.

The invention provides, in one aspect, a film cooled insert for aperture 22 to prevent or minimize the noted cracking. One preferred insert is schematically illustrated in FIG. 4.

FIG. 4 illustrates one preferred embodiment of a combustor liner insert 40 according to the invention. Liner insert 40 comprises an outer short cylindrical sleeve or ring 41 of about 0.36 in.(9mm) height, about 1.38 in.(34.5mm) I.D. and about 1.5 in.(38mm) O.D. Fitted within cylindrical sleeve 41 is a flared or bell mouth sleeve 42 comprising a lower cylindrical section 43 and an upper flared or bell mouth section 44 which is continuous with section 43. The flaring of section 44 continues until the flare defines an annular lip 45, whose plane is perpendicular to the longitudinal axis of cylindrical section 43. In one practice of this invention, lip 45 was formed with 0.25 in.(6.5mm) radius. In addition, the O.D. of cylindrical

section 43 of sleeve 42 is significantly less than the I.D. of first sleeve 41 so that sleeve 42 may be axially inserted into sleeve 41 and moved into an eccentric position until the cylindrical section 43 of sleeve 42 engages the inner wall of sleeve 41 and the lower square edge 48 of sleeve 42 projects through the plane of the lower square edge 47 of sleeve 41. In this position the lower square edge 47 of sleeve 41 is in staggered relationship to lower edge 48 of sleeve 42 (extending beyond it, for example, from about .06 in. (1.5mm) to about .12 in. (3.0mm), preferably the latter) but may be coplanar therewith. The inner and outer walls of sleeve 41 meet at a sharp edge 49 at the upper end thereof.

At the eccentric juncture of the two sleeves, an appropriate weld, braze or other suitable fastening technique joins sleeves 41 and 42 into an integral insert. While welding or brazing of two separate cylinders is a convenient manufacturing method for the insert of the present invention, the insert 40 may be manufactured, for example, as a single piece, by means of a metal casting process. As described, the insert of this invention may be produced by various manufacturing processes utilizing a variety of component parts. Broadly described, with respect to FIG. 4, for example, these processes provide a basic insert having a first wall 43 defining a cylindrical air flow passage for a flow of air axially through the insert and a second wall 41 in cooperative relationship with, and spaced from, the first wall to define a radially crescent shaped but axially directed air flow passage in adjacent and slide by slide relationship to the cylindrical flow passage so that a flow of air through the crescent passage is in contact with the first wall, with the first wall 43 having a flared lip overlying but spaced from the crescent shaped opening 46.

In FIG. 5, which is an axial view of FIG. 4 taken along the line 5-5 thereof, the crescent space 46 is more clearly illustrated and the center lines indicate eccentricity of sleeves 41 and 42. As shown in FIG. 4, annular lip 45 overlies sharp edge 49 but is spaced therefrom to define a peripheral or lateral opening into crescent space 46.

In one practice of this invention cylindrical section 41 had an O.D. of about 1.5 in. (38.0mm), and the cylindrical section 43 of sleeve 42 had an O.D. of about 1.2 in. (30.5mm). Wall thickness of both sleeves was from about .030 to .040 in. (0.8 to 1.00mm).

As illustrated in FIG. 4, the lower edge of sleeve 41 is a square edge 47. At the upper edge of sleeve 41 the inner surface of sleeve 41 tapers or curves outwardly to contact the outer surface of a sharp or taper edge 49. The lower edges or inner ends of both sleeves 41 and 42 may be staggered as illustrated in FIG. 6.

The described intervening space 46 between the I.D. of sleeve 41 and the O.D. of sleeve 42 is utilized as an air flow channel. Insert 40 is placed in an aperture 22 of liner 15 with the widest part of the crescent space exposed directly to the air flow from compressor 11 in annular space 21. This arrangement provides the air flow pattern as illustrated in

FIG. 6. Referring now to FIG. 6, the insert 40 of this invention is illustrated in its assembled position in an aperture 22 of liner 15 with the lip 45 part of sleeve 42 projecting above the periphery of liner 15 and into annular space 21 (FIG. 1). The largest opening of the crescent shaped space 46 between sleeves 41 and 42 is positioned to be directly exposed to the air flow from the compressor 11 (FIG. 1) as noted in FIG. 6 by the appropriate labeling and associated flow arrows. As previously described with respect to FIG. 1, air flow from space 21 is caused to turn a first 90 degrees and move through apertures 22, and when the insert 40 of this invention is utilized, the described air flow turns through a first 90 degrees to move through the insert 40. The distance which square edge 48 of sleeve 42 projects through the plane of edge 47 of sleeve 41 has some effect on the depth that the air flow through the insert 40 penetrates into the combustion gas flow in liner 15. The lip part 45 of sleeve 42 in conjunction with sharp edge 49 of sleeve 41 deflects a part of the air flow through the crescent space 46 and not only maintains sleeve 41 and the adjacent periphery of sleeve 42 at a relatively cool temperature, but also maintains the periphery of aperture 22 at a cooler and constant temperature. The pre-existing temperature differential in the surrounding surface or perimeter of apertures 22 is believed to have been a contributory factor to the cracking illustrated and described with respect to FIG. 3.

A cross-sectional view of an operative embodiment of this invention is illustrated in FIG. 7 in which an insert 40 (FIG. 4) of this invention is assembled in an aperture 22 in the liner of the above described FIG. 2. Flow arrows in FIG. 7 illustrate lip 45 deflecting some air flow into crescent space 46 with the main air flow passing through sleeve 42 to ameliorate the causes for cracking illustrated in FIG. 3. In practice an insert 40 may be placed in all apertures 22, or of a liner or only in those rows of apertures or certain apertures which are most prone to cracking problems. Ordinarily a plurality of inserts 40 are utilized in each liner.

In summary, the use of an insert 40 of this invention in an aperture 22 adds some uniformity to the temperature distribution about the periphery of an aperture 22, prevents flow separation of the air flow turning from annular space 21 into and through apertures 22 and, as a consequence, tends to prevent or minimize deleterious cracking as described. In addition, insert 40 of this invention includes a very high air flow coefficient so that the prior normal or required air flow into liner 15 is not significantly altered or diminished. Air flow discharge coefficients range from about 0.6 to about 0.75 based on ordinary and usual air velocity and pressure values found in annular space 21 (FIG. 1) and within liner 15, depending on the air flow velocities and pressures outside and inside a liner adjacent an air inlet aperture. The air flow discharge coefficient C is defined as

FIG. 6. Referring now to FIG. 6, the insert 40 of this invention is illustrated in its assembled position in an aperture 22 of liner 15 with the lip 45 part of sleeve 42 projecting above the periphery of liner 15 and into annular space 21 (FIG. 1). The largest opening of the crescent shaped space 46 between sleeves 41 and 42 is positioned to be directly exposed to the air flow from the compressor 11 (FIG. 1) as noted in FIG. 6 by the appropriate labeling and associated flow arrows. As previously described with respect to FIG. 1, air flow from space 21 is caused to turn a first 90 degrees and move through apertures 22, and when the insert 40 of this invention is utilized, the described air flow turns through a first 90 degrees to move through the insert 40. The distance which square edge 48 of sleeve 42 projects through the plane of edge 47 of sleeve 41 has some effect on the depth that the air flow through the insert 40 penetrates into the combustion gas flow in liner 15. The lip part 45 of sleeve 42 in conjunction with sharp edge 49 of sleeve 41 deflects a part of the air flow through the crescent space 46 and not only maintains sleeve 41 and the adjacent periphery of sleeve 42 at a relatively cool temperature, but also maintains the periphery of aperture 22 at a cooler and constant temperature. The pre-existing temperature differential in the surrounding surface or perimeter of apertures 22 is believed to have been a contributory factor to the cracking illustrated and described with respect to FIG. 3.

A cross-sectional view of an operative embodiment of this invention is illustrated in FIG. 7 in which an insert 40 (FIG. 4) of this invention is assembled in an aperture 22 in the liner of the above described FIG. 2. Flow arrows in FIG. 7 illustrate lip 45 deflecting some air flow into crescent space 46 with the main air flow passing through sleeve 42 to ameliorate the causes for cracking illustrated in FIG. 3. In practice an insert 40 may be placed in all apertures 22, or of a liner or only in those rows of apertures or certain apertures which are most prone to cracking problems. Ordinarily a plurality of inserts 40 are utilized in each liner.

In summary, the use of an insert 40 of this invention in an aperture 22 adds some uniformity to the temperature distribution about the periphery of an aperture 22, prevents flow separation of the air flow turning from annular space 21 into and through apertures 22 and, as a consequence, tends to prevent or minimize deleterious cracking as described. In addition, insert 40 of this invention includes a very high air flow coefficient so that the prior normal or required air flow into liner 15 is not significantly altered or diminished. Air flow discharge coefficients range from about 0.6 to about 0.75 based on ordinary and usual air velocity and pressure values found in annular space 21 (FIG. 1) and within liner 15, depending on the air flow velocities and pressures outside and inside a liner adjacent an air inlet aperture. The air flow discharge coefficient C is defined as

EMI ID = 15/1 HE = 16 WI = 30 TI = MAT

5 6

where M_4 is the actual air flow rate through the liner aperture and M_5 is the calculated theoretical flow rate. While this invention has been illustrated and described with respect to a preferred embodiment and use thereof, it will be apparent to those skilled in the art that various modifications may be made without departing from the scope of the appended claims.

Claims

1. An insert to direct air through an aperture comprising in combination:
 - (a) a first wall defining a cylindrical air flow passage axially through said insert;
 - (b) a second wall in cooperative relationship with said first wall and spaced therefrom to define a radially crescent shaped but axially directed air flow passage in adjacent relationship to said cylindrical air flow passage to enable the flow of air through said crescent passage, in contact with said first wall,
 - (c) said first wall having a lip portion overlying the crescent passage to define an air entry thereto.
2. The invention as recited in Claim 1 wherein said air entry is laterally arranged with respect to said cylindrical flow passage.
3. A gas turbine combustion system combustor liner comprising in combination:
 - (a) a tubular wall combustor liner,
 - (b) said liner having axially spaced circumferential rows of circular apertures in the tubular wall thereof,
 - (c) and a film cooled insert in some of said circular apertures in said liner, said insert comprising
 - i. a first short cylindrical sleeve member having an O.D. appropriate for insertion in said circular apertures in said liner,
 - ii. a second sleeve member having a cylindrical squared section at its inner end at one end and a catarinuous radially outwardly flared section at the other end,
 - iii. said second sleeve member being inserted and positioned axially in said first sleeve member in eccentric relationship thereto so that said second sleeve member comes into radial contact with said first sleeve member to define a radially crescent shaped but axially directed flow passage between said first and second sleeve members,
 - iv. said radially flared section of said

5 65

second sleeve member defining an annular lip surrounding said sleeve member with the plane of said lip perpendicular to the longitudinal axis of said second sleeve.

v. said cylindrical section of said second sleeve member having an O.D. less than the I.D. of said first cylindrical sleeve member and vi. joining means joining said sleeves to each other at their eccentric contact juncture.

4. The invention as recited in Claim 3 wherein said insert is inserted in said liner so that the said first cylindrical section is concentrically positioned in said liner aperture and joined to the perimeter of said aperture so that the said annular lip of said second sleeve projects above the periphery of said liner.

5. The invention as recited in Claim 3 wherein said first cylindrical section is positioned in said liner aperture to project into said liner.

6. The invention as recited in Claim 3 wherein said first cylindrical sleeve member wall has a substantially square edge at one end and a sharp edge at the other end, and wherein said annular lip overlies said sharp edge in spaced relation thereto to define a peripheral opening into said crescent shaped axial flow passage.

7. The invention as recited in Claim 3 wherein the inner end of said short cylindrical sleeve member and the inner end of said second sleeve member are substantially coplanar.

8. The invention as recited in Claim 3 wherein said insert is positioned in said liner so that said peripheral opening into said crescent passage is on the side of said insert directly exposed to the direction of air flow in said passage between said liner and said casing.

9. The invention as recited in Claim 7 wherein said ends are staggered relationship.

10. The invention as recited in Claim 9 wherein the inner end of said sleeve member projects through the plane of the square edge end by from about .06 in. to about .12 in. (1.5 to 3.0mm).
